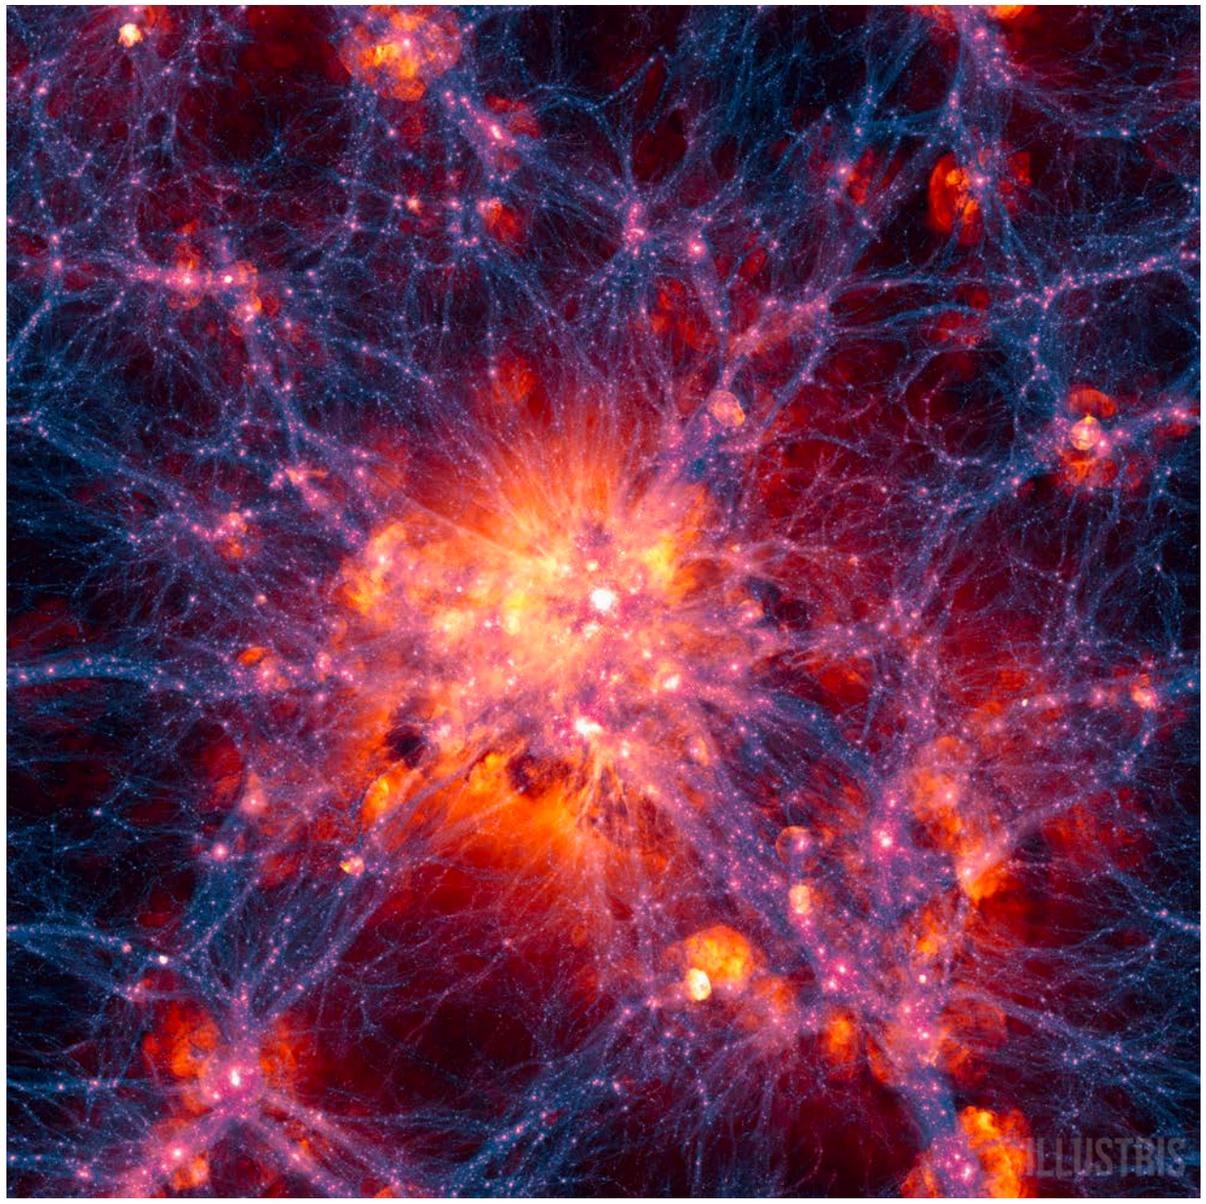
Large Scale Simulations



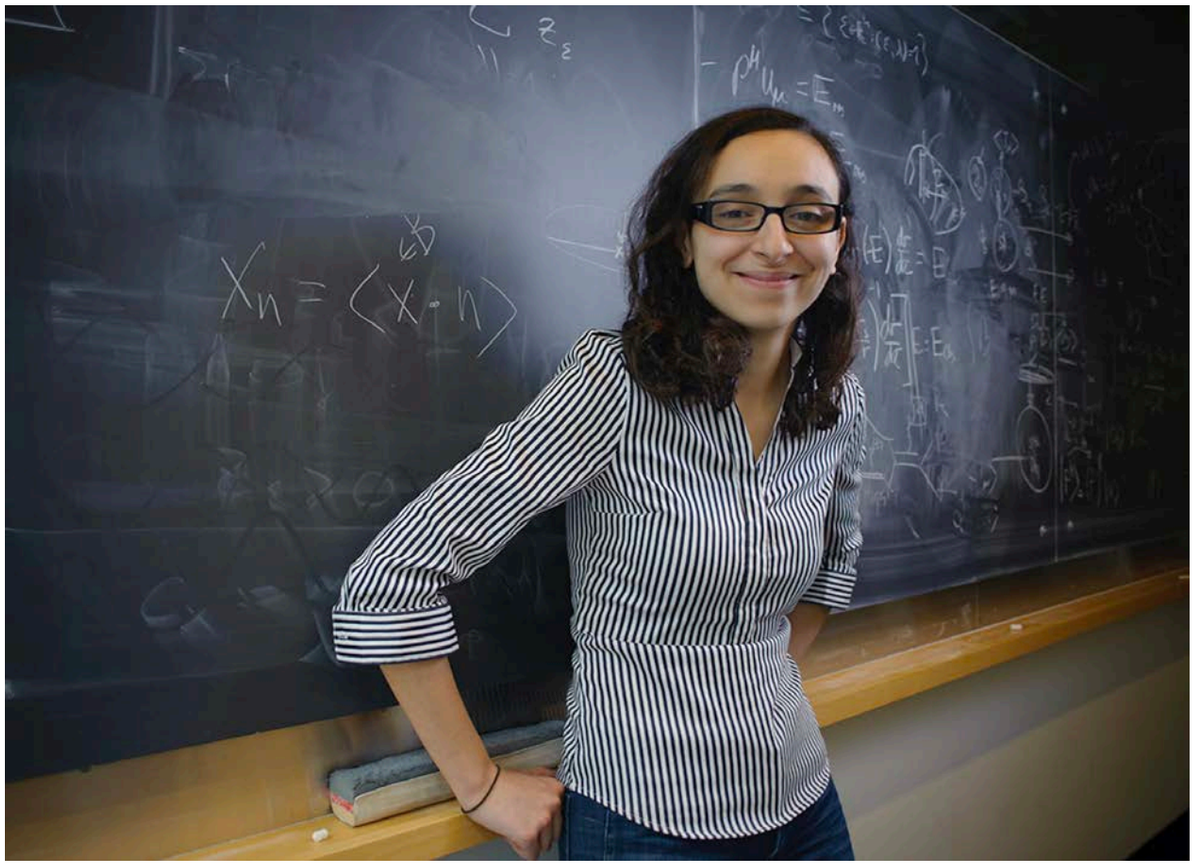
Our Goal In Lecture

- Going to build up the intuition for large-scale simulation
  - Focus on the simulation of galaxies to the universe
  - This lecture will give the tools to do this
- The devil is in the details
  - Our lecture use the core concepts in large scale sim
  - To get everything to work at scale is much harder
- We will touch on where the field is going

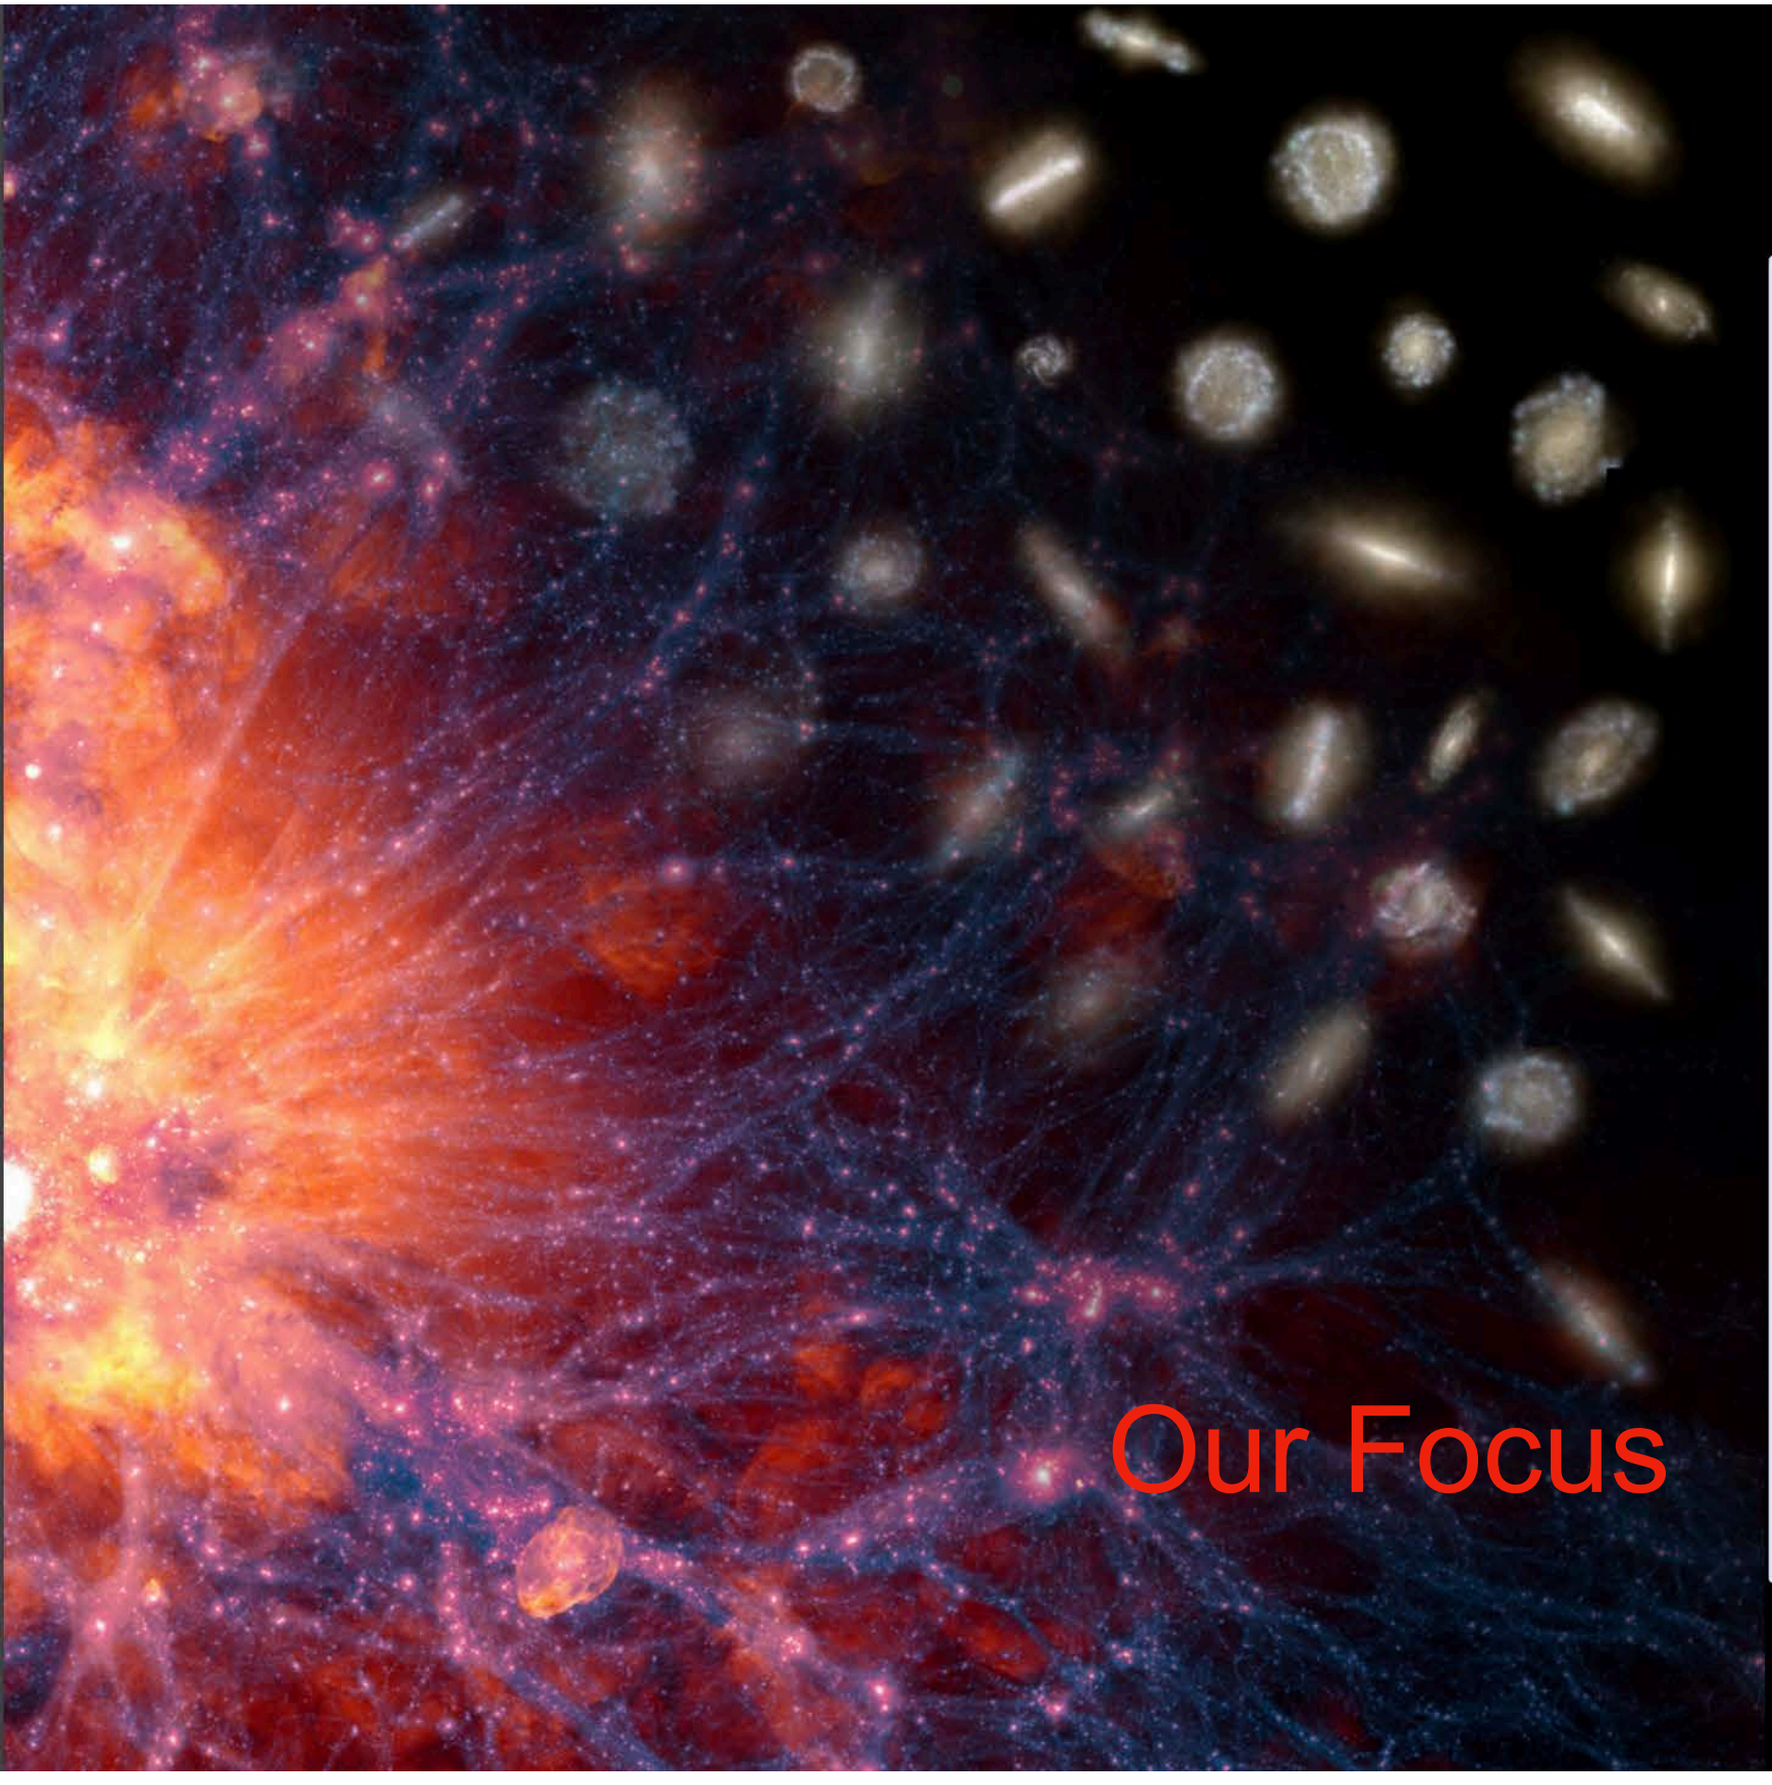
Lets Take a look at the Scale of Things

- https://www.illustris-project.org/media/

Prof. Mark Vogelsberg
Main Inspiration for talk



Prof. Lina Necib
Doing related work on smaller scales



Illustris/IllustrisTNG Model:
- basic ingredients -

- **hydrodynamics:**
  quasi-Lagrangian moving mesh (Arepo, Springel 2010)
- **heating / cooling:**
  primordial, metal line
- **UV background:**
  with self-shielding correction
- **star formation / ISM:**
  effective EOS
- **chemical enrichment:**
  9 elements by SNIa, SNII, AGB
- **supernova feedback:**
  kinetic SNII feedback
- **supermassive black holes:**
  seeding, growth, merging
- **AGN feedback:**
  quasar, radio mode, radiative

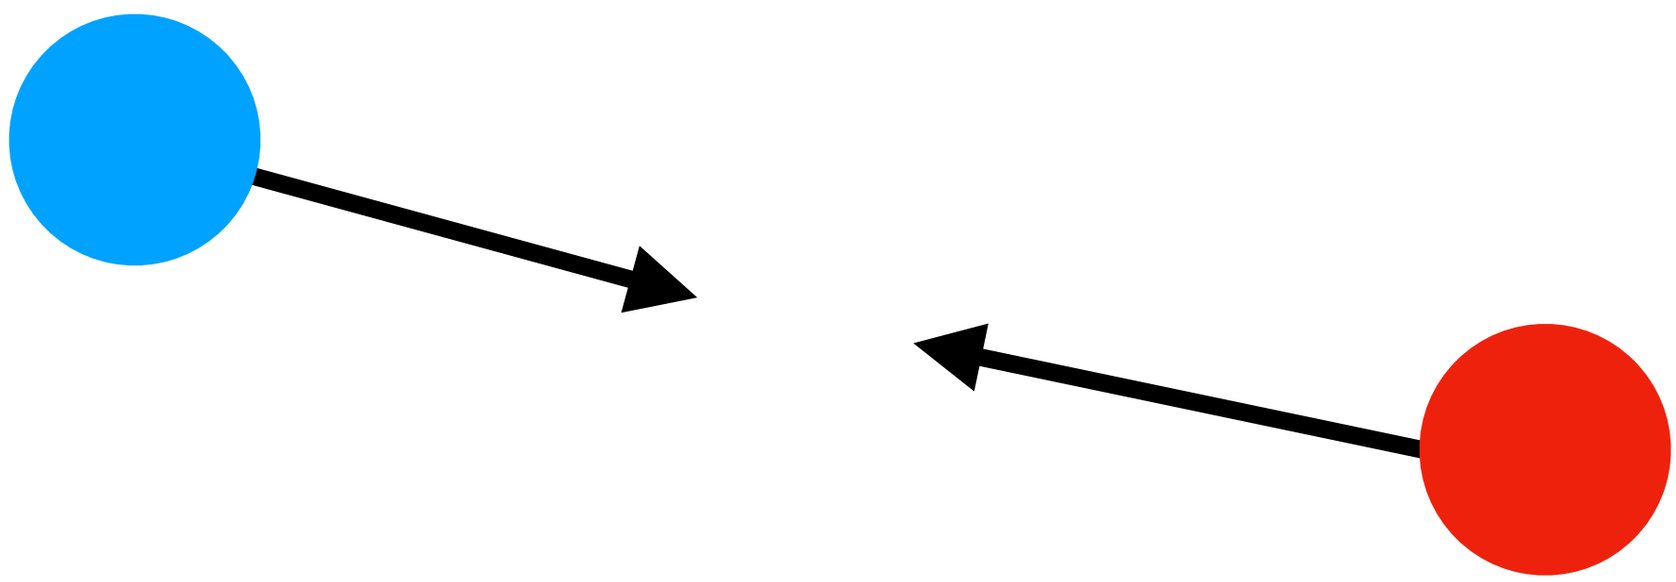
Details

- This lecture is built on the following references:
  - https://www.youtube.com/watch?v=Fo23ihGLPA0
  - https://td.lpi.ru/~eugvas/nbody/lectures.pdf
  - https://www.tat.physik.uni-tuebingen.de/~schaefer/teach/f/chaos_english.pdf
  - https://blbadger.github.io/3-body-problem.html

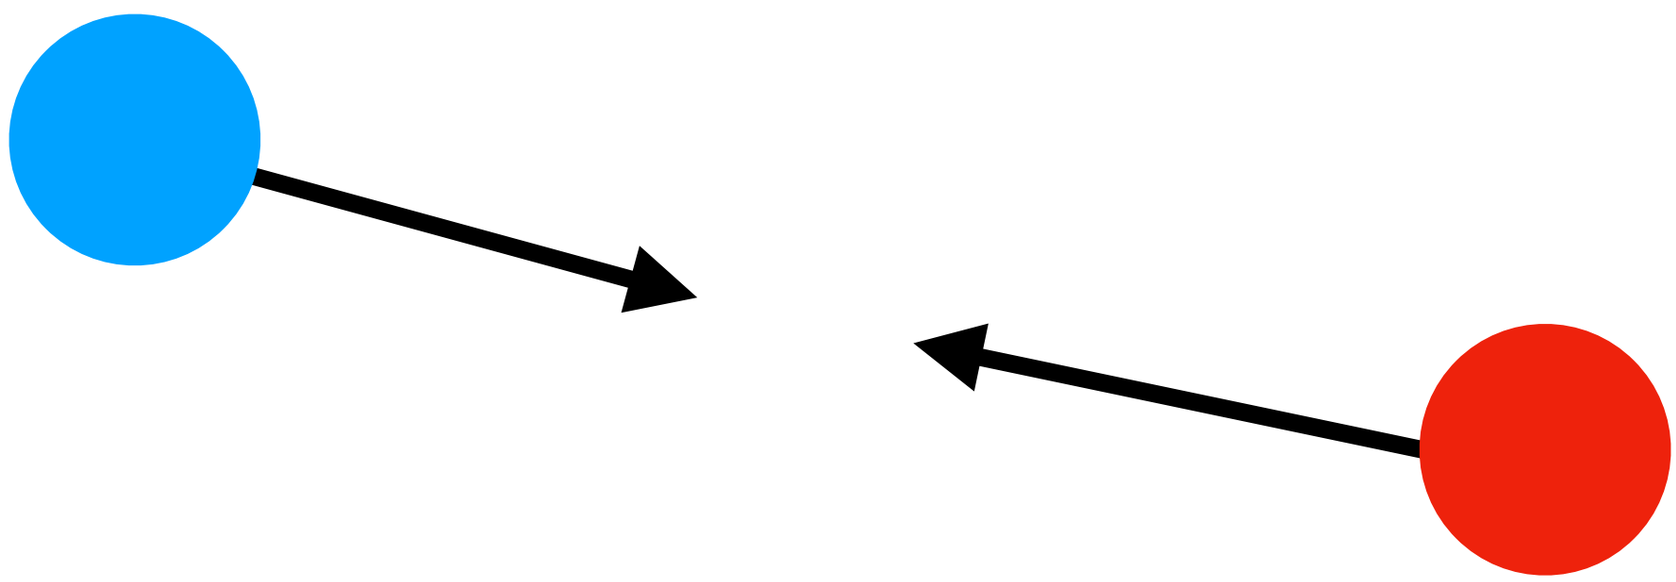
What do we need for Simulation?



$$F = \frac{G m_1 m_2}{|\vec{r}_1 - \vec{r}_2|^3} (\vec{r}_1 - \vec{r}_2)$$

- All Physics we need has been developed 100s of years ago
  - The two body problem has been solved since the 18th century

What do we need for Simulation?



$$F = \frac{G m_1 m_2}{|\vec{r}_1 - \vec{r}_2 + \epsilon|^3} (\vec{r}_1 - \vec{r}_2)$$

- To simulate this on a computer we will add a “softening” term

This is how DM/galaxies are modeled

- Instead of treating matter as a fluid
  - Discretize matter into chunks and solve n-body problem

Monte Carlo Approach

→ discretize in terms of N simulation particles, which sample distribution function

→ follow the equation of motion of these sample particles

$$\ddot{\mathbf{x}}_i = -\nabla_i \Phi(\mathbf{x}_i)$$ ← equation of motion for particle i

$$\Phi(\mathbf{x}) = -G \sum_{j=1}^{N} \frac{m_j}{[(\mathbf{x} - \mathbf{x}_j)^2 + \epsilon^2]^{1/2}}$$ ← collective potential

↑ softening

→ N is much smaller than the 'real' N

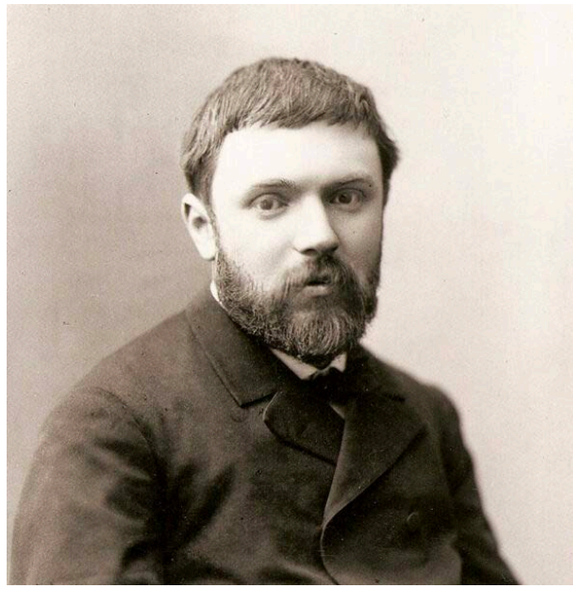
→ this low N can cause large-angle particle scatterings and formation of bound pairs

→ add softening to avoid these effects

→ softening to mimic collisionless system evolving according to Poisson-Vlasov

3 body Problem: History

- The original two body probelm was solved in 18th century
  - Work done by Netwon, Bernoulli Bros, Euler, Laplace,…
    - All started on the 3 body problem and built on the two body
- King Oscar II decided to make a competition:
  - For his 60th birthday he bestowed a prize on who could solve the n-body problem



3 body Problem: History

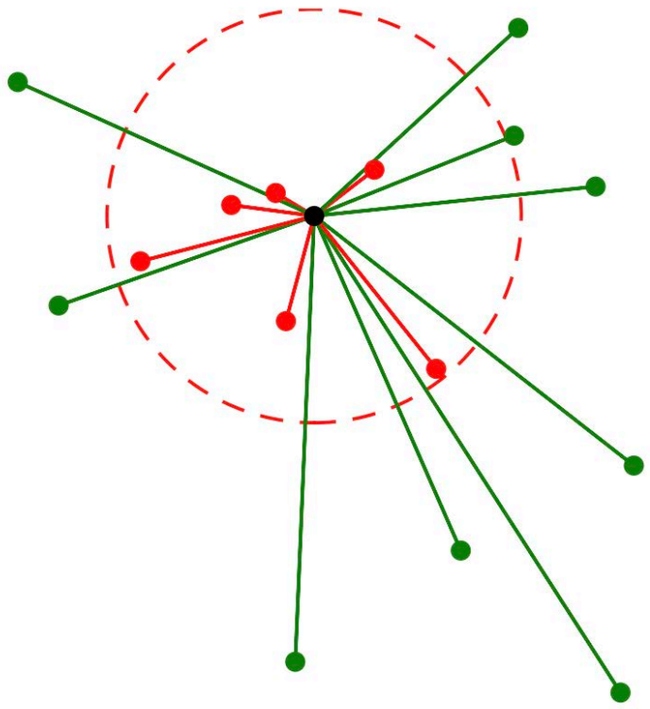
- The original two body probelm was solved in 18th century
  - Work done by Netwon, Bernoulli Bros, Euler, Laplace,…
    - All started on the 3 body problem and built on the two body
- King Oscar II (king of Sweden) decided to make a competition:
  - For his 60th birthday he bestowed a prize on who could solve the n-body problem

Henri Poincare →

He proved no solution existed!

Going to N-body

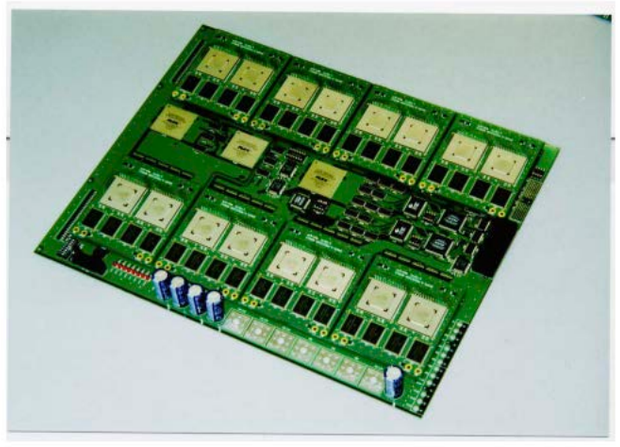
- The challenge of solving this numerically for n-body
  - This scales with the number of bodies N^2
  - Requires the computations of all pairwise distances

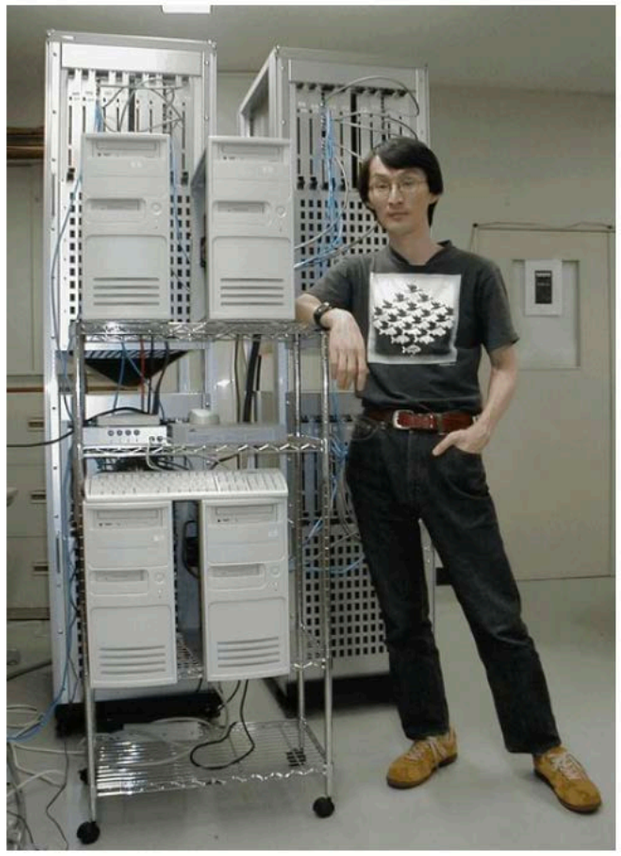


- For N=1000 (1 Million/step computations)
- For N=10^6 Something ridiculous

Historical Solutions

- One approach has been to build dedicated computing hardware
  - Dedicated hardware that can do large-scale parallel computation
  - Focused specifically on n-body simulation
  - GRAPE boards (GRAvity PipelinE)
- Now done with GPUs





Jun Makino with GRAPE-6

Scaling of n-body

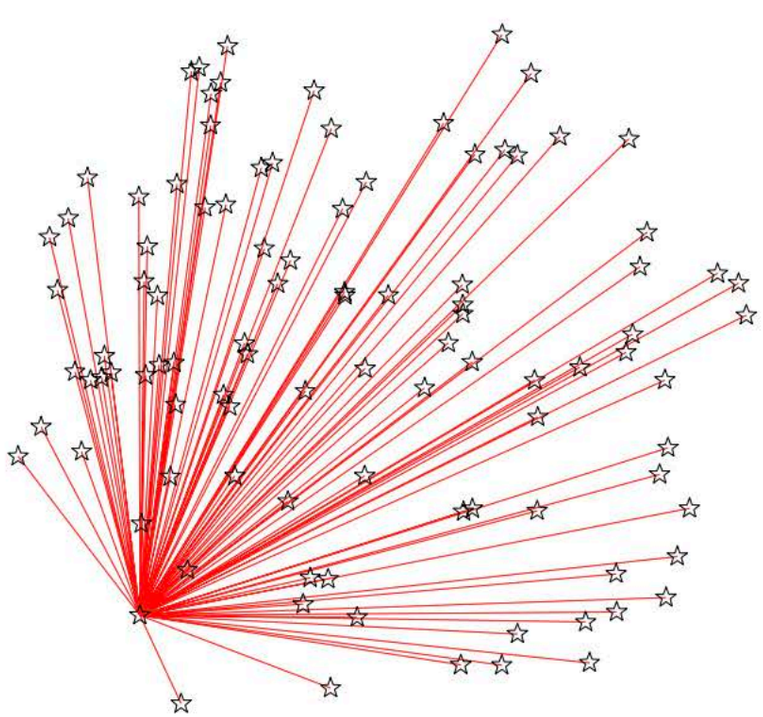
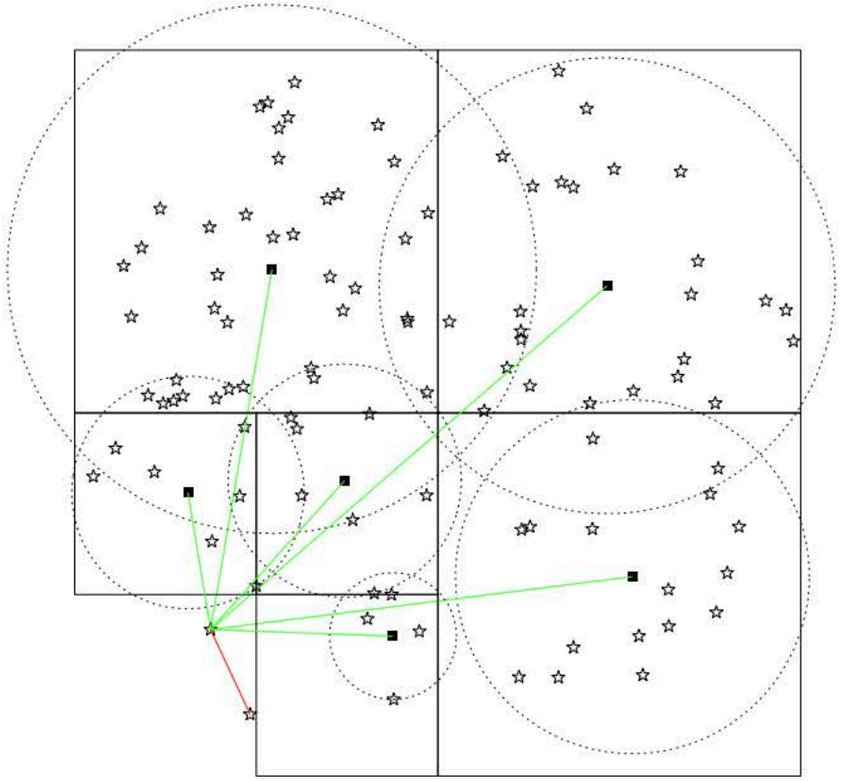
How do you deal with N-body?

- Barne's-Hut Algorithm re-rank stars into a tree structure
  - Structure is a grid over the whole space

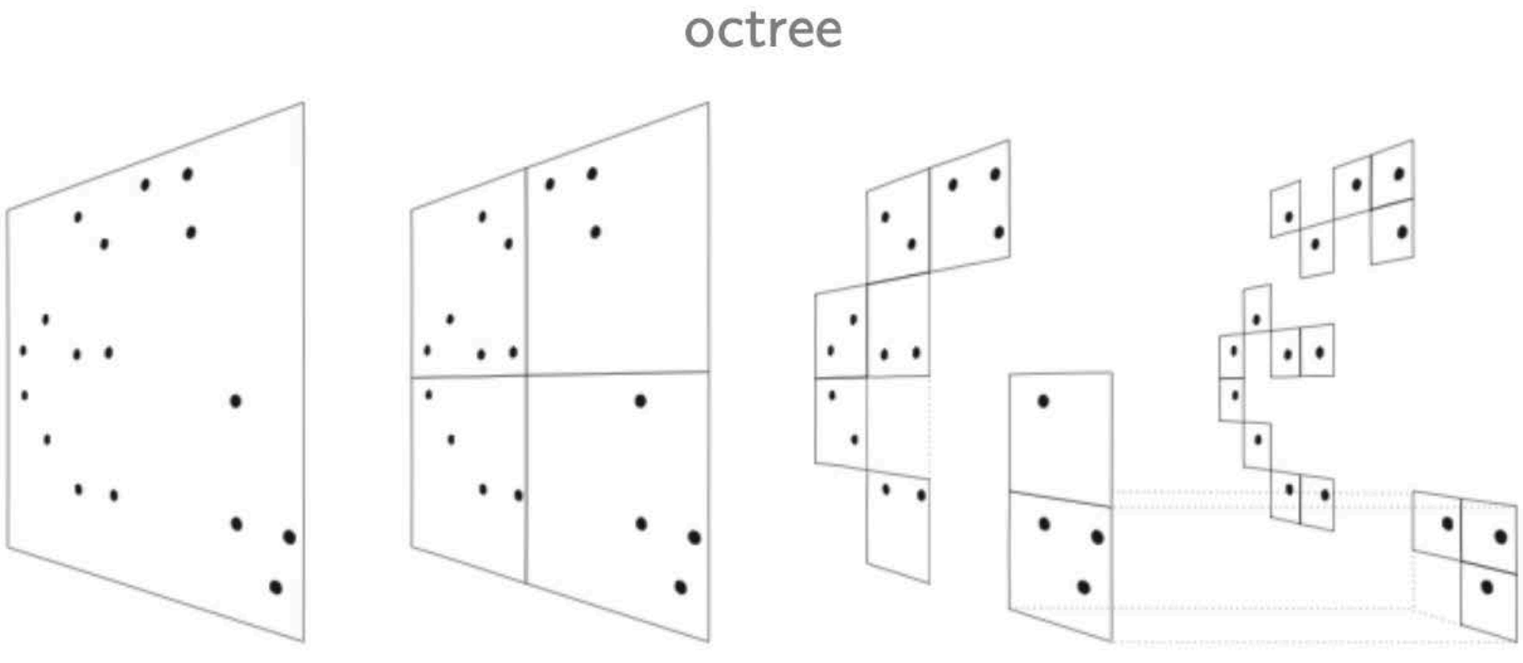


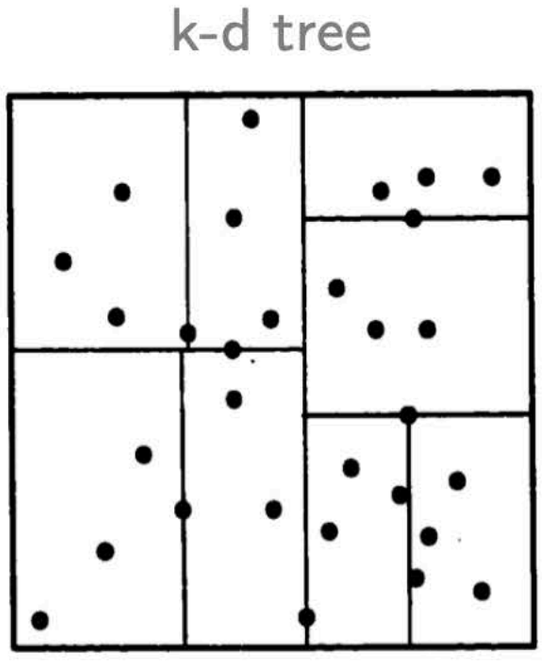


[from Dehnen & Read 2011]

Tree Construction

- QuadTree/OctTree
  - Split each square(cube) into 4(8) sub regions
- KD Tree
  - Use the data to draw equal numbered regions in space

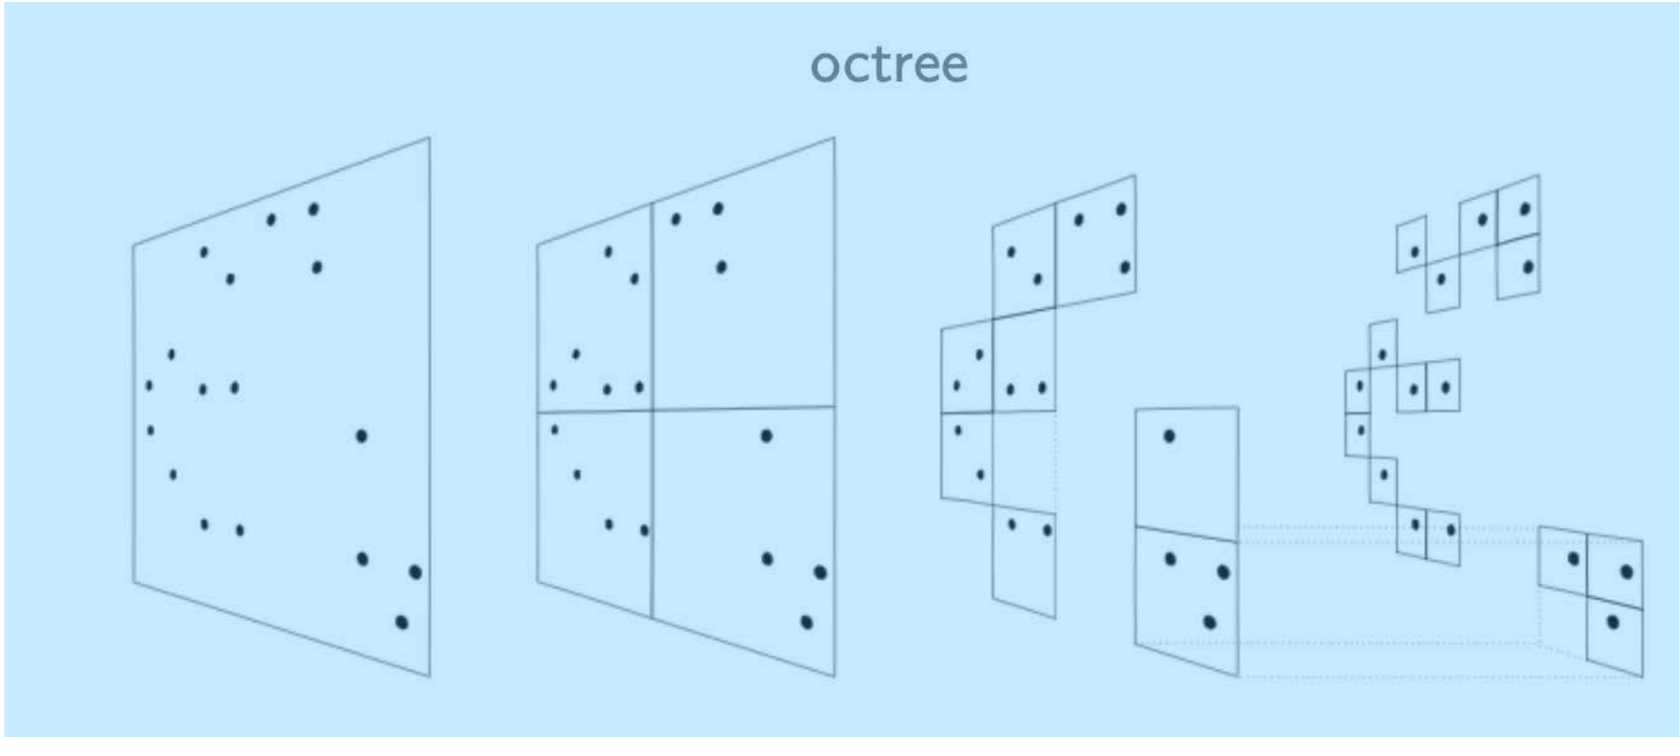


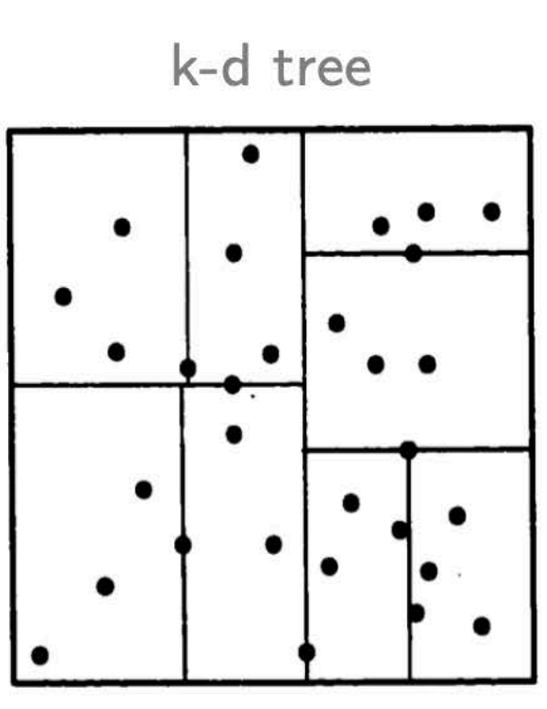


Tree Construction

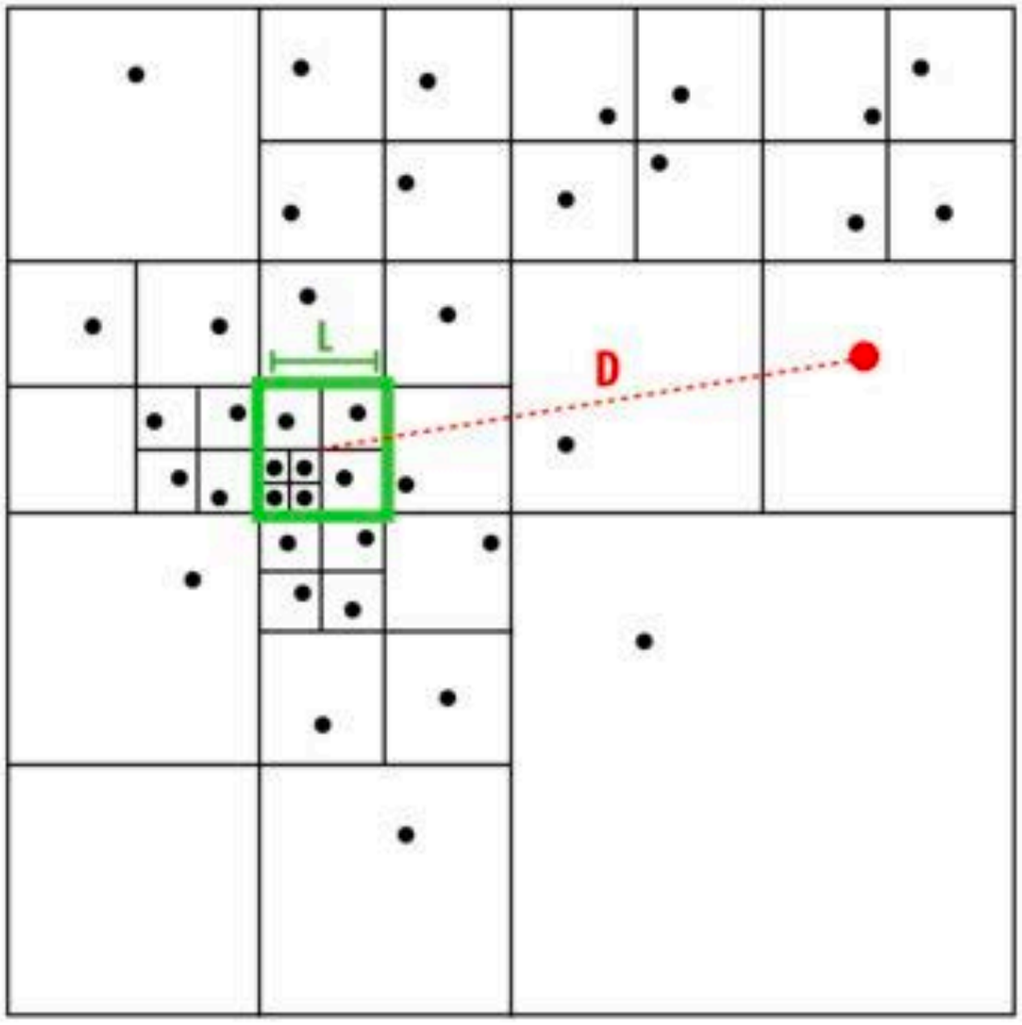
- QuadTree/OctTree
  - Split each square(cube) into 4(8) sub regions
- KD Tree
  - Use the data to draw equal numbered regions in space

Just requires that we know the bounds of the space

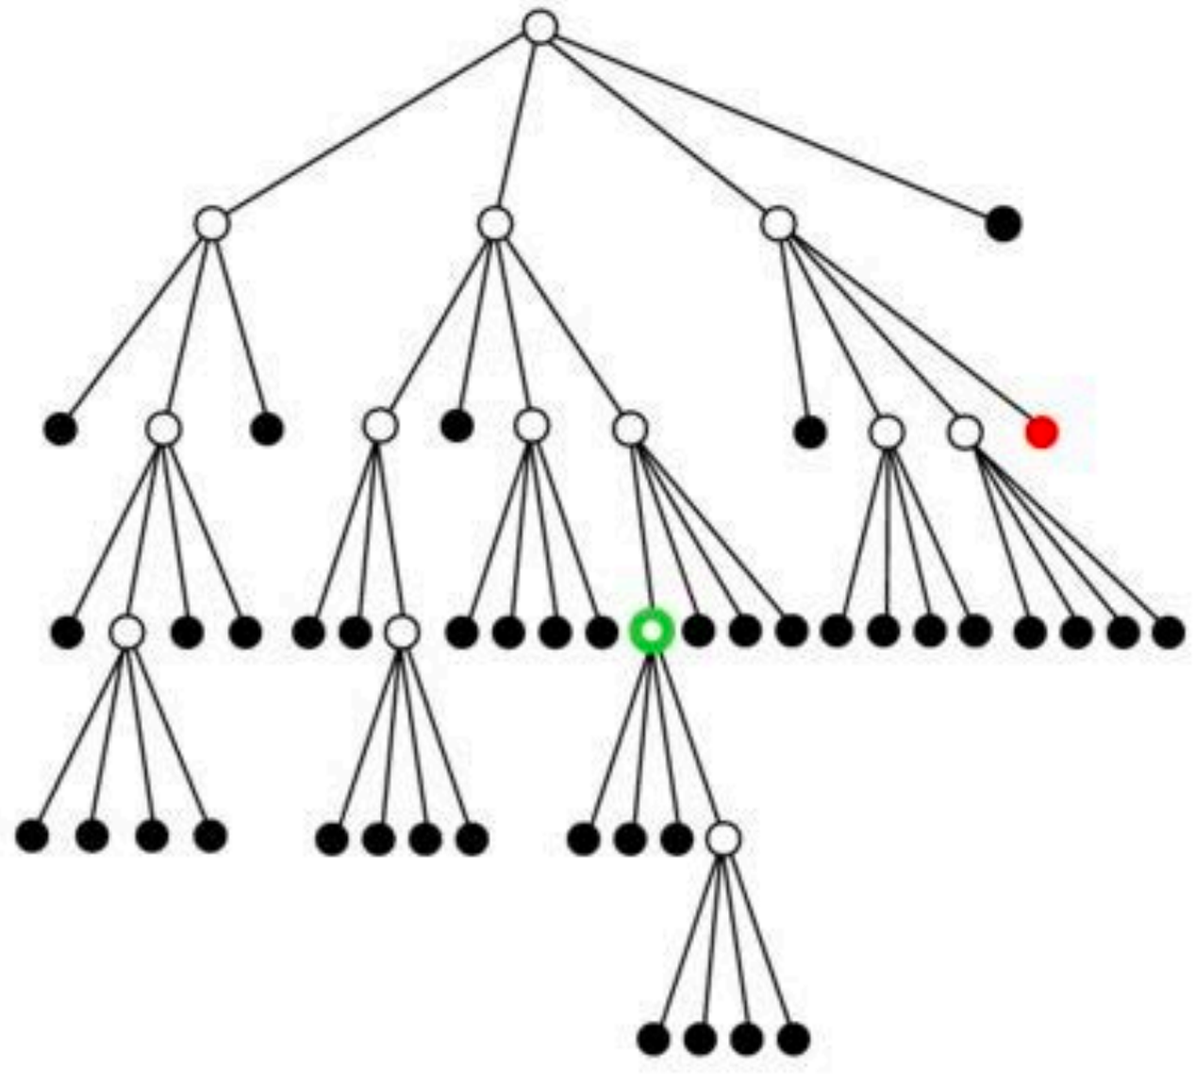




Visualizing Tree



Spatial Domain



Quad-Tree Representation

Note that for the big grids, this equates to Gauss' law style an apporach
Treat each square as a star w/total mass at mass weighted center

Barnes-Hut Algorithm

- We can follow a step by step construction of this :
  - 1. Construct tree structure with bounds
  - 2. Loop over stars and fill tree structure
  - 3. Loop over stars and compute distance
    - Full n-body computation for nearby trees only
  - 4. Step forward everything
- The above process is N log(N) in comptuational time
